

Functions

Due this week

- **Homework 4**

- Write solutions in VSCode and paste in Autograder, **Homework 4 CodeRunner**.
- Zip your .cpp files and submit on canvas **Homework 4**. Check the due date!
No late submissions!!

- **3-2-1 due Friday**

- No Quiz this week

Today

- What are functions?
- Implementing functions
- Function parameters and arguments

Functions

What is a function?

- A function
 - is a sequence of instructions with a name
 - packages a computation into a form that can be easily understood and reused
- example:

```
int main()  
{  
double z = pow(2, 3);  
...  
}
```

Functions as Black Box

- You can think of a function as a “black box”
 - Know what the box does, but can't see what's inside
 - Like a pressure cooker -- can't see inside, know what it does

Functions as Black Box

- You can think of a function as a “black box”
 - Know what the box does, but can’t see what’s inside
 - Like a pressure cooker -- can’t see inside, know what it does

Example: How did the pow function do its job?

→ You didn’t need to know in order to use it

→ You only need to know its specification (inputs/outputs, syntax)

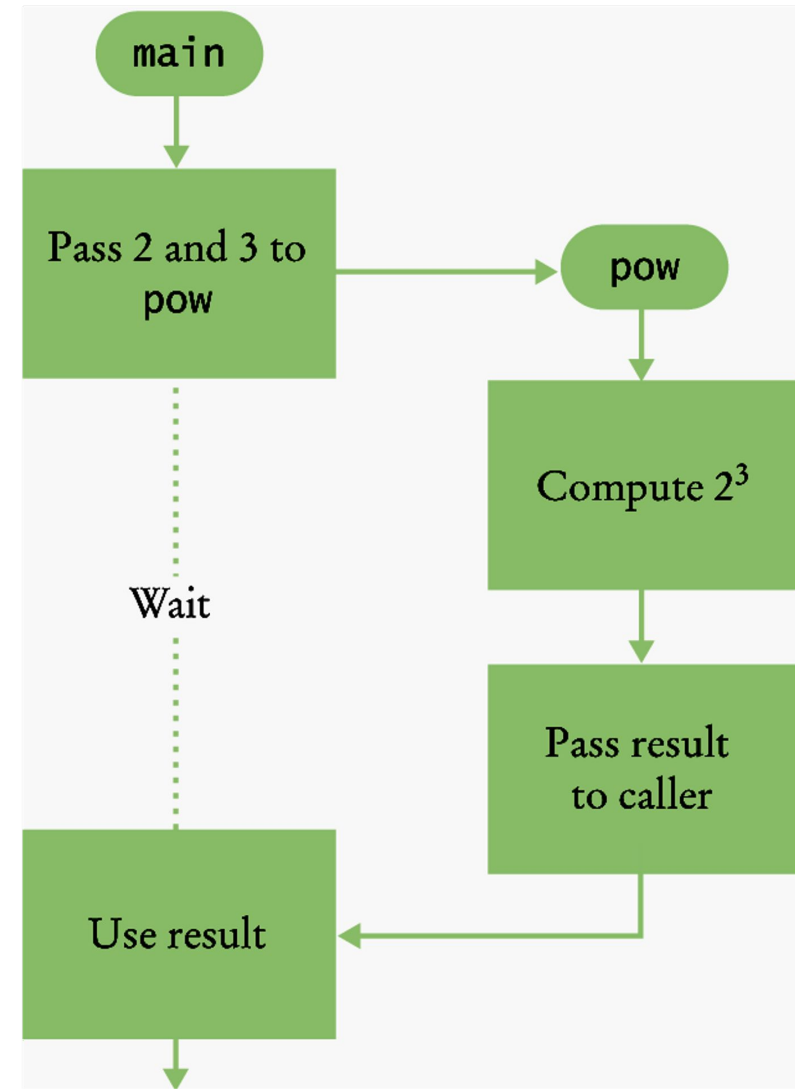

Calling a function

- main is a function, and so is pow
- main calls the pow function, asking it to compute 2^3
- The main function is temporarily suspended while pow does its thing
- The instructions of the pow function execute and compute the result
- The pow function returns its result back to main
- main resumes execution

```
int main()  
{  
    double z = pow(2, 3);  
    ...  
}
```

Flowchart: Calling a function

Execution flow during a function call

Actual parameters/arguments

- When another function calls the pow function, it provides inputs
 - (e.g., the 2 and 3 in the call pow(2, 3))
- In order to avoid confusion with user-provided inputs (cin >>), these values are called **function arguments**
- The output that the pow functions computes is called the return value
 - (as opposed to output using cout <<)

```
int main()  
{  
    double z = pow(2, 3);  
    ...  
}
```

Parameters

Note: An output statement (cout) does not return a value and the return statement does not display output

- output \neq return
- return statement ends the called function and resumes execution of the program that called that function
 - Can also pass a value back to the calling program (e.g., return 0;)
- A cout << statement communicates only with the user running the program
 - Just spits things out to the screen. That's it.

Implementing functions

Example: Calculate the volume of a cube

- 1) Pick a good descriptive name for the function
- 2) Give a type and name for each parameter

There will be one parameter for each piece of information the function needs to do its job

- 3) Specify the type of the return value:

double cube_volume(double side_length);

- 4) Then write the body of the function, as statements enclosed in curly braces { ... }

Implementing functions

Example: Calculate the volume of a cube

Note: Useful comments at the top: description, parameters, return, algorithm

```
/*  
    Computes the volume of a cube  
    @param side_length -- the side length of the cube  
    @return the volume of the cube  
*/  
double cube_volume(double side_length)  
{  
    double volume = side_length * side_length * side_length;  
    return volume;  
}
```

Implementing functions

- How do you know your function works as intended??
 - You should always test the function
 - Write a main() function to do this
 - Let's test a couple different side_lengths for our cube_volume function and see if it outputs the correct volumes

```
int main()
{
    double result1 = cube_volume(2);
    double result2 = cube_volume(10);
    cout << "A cube with side length 2 has volume " << result1 <<
    endl;
    cout << "A cube with side length 10 has volume " << result2 <<
    endl;
    return 0;
}
```

Parameter Passing

Parameter Passing

- When a function is called, a *parameter variable* is created for each value passed in.
- Each parameter variable is *initialized* with the corresponding parameter value from the call.

```
int hours = read_value_between(1, 12);
```

```
...
```

```
int read_value_between(int low, int high);
```

Parameter Passing

- When a function is called, a *parameter variable* is created for each value passed in.
- Each parameter variable is *initialized* with the corresponding parameter value from the call.

```
int hours = read_value_between(1, 12);
```

```
. . .
```

```
int read_value_between(int low , int high)
```

Parameter Passing

- Example: A call to our `cube_volume` function:

```
double result1 = cube_volume(2);
```

- Here is the function definition:

```
double cube_volume(double side_length)
{
    double volume = side_length * side_length * side_length;
    return volume;
}
```

- Let's keep track of the variables and their parameters:

```
result1, side_length, volume
```

Parameter Passing – the play-by-play

- **First**, the function call: `double result1 = cube_volume(2);`

→ `result1 = _____ side_length = _____`

Parameter Passing – the play-by-play

- **First**, the function call: `double result1 = cube_volume(2);`

→ `result1 = _____ side_length = _____`

- **Second**, initializing function parameter variable: `double result1 = cube_volume(2);`

→ `result1 = _____ side_length = 2`

Parameter Passing – the play-by-play

- **Third, execute** `cube_volume` **function:**

```
double volume = side_length * side_length * side_length;  
return volume;
```

→ `result1 = _____` `side_length = 2` `volume = 8`

Parameter Passing – the play-by-play

- **Third, execute** `cube_volume` function:

```
double volume = side_length * side_length * side_length;  
return volume;
```

→ `result1 = _____` `side_length = 2` `volume = 8`

- **Finally, after the function call:** `double result1 = cube_volume(2);`

→ `result1 = 8`

Parameter Passing

- In the calling function (`main`), the variable `result1` is declared.
- When the `cube_volume` function is called, the parameter variable `side_length` is created & initialized with the value that was passed in the call (2).
- After the return statement, the local variables `side_length` and `volume` disappear from memory.
- The calculated volume is stored in the variable, `result1`
