#### OTTER THIS WORLD

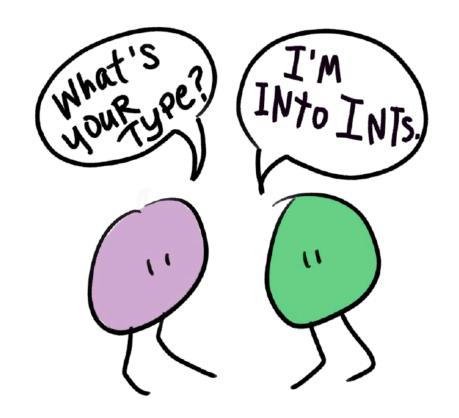

The reason why world never says hello back!!

# Variables and Arithmetic

#### Due this week

#### Recitation 1

- Write pseudocode
- Homework 1
  - Submit pdf file on Canvas. PDF
- Quiz 2
- 3-2-1 reflection on Friday
- Check the due date!

# Today

- Mental Models: how do computers work?
- Variables
- Errors

# How do computers work?

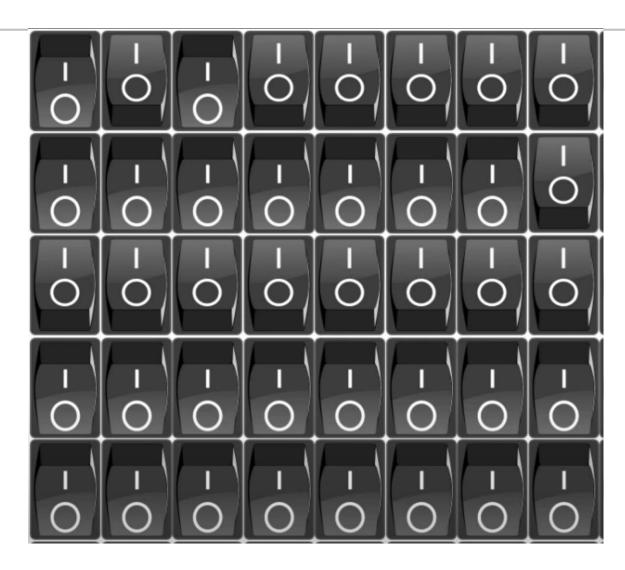

## Computers are Walls of Switches

• RAM:

Random

Access

Memory

#### Columns (CAS)

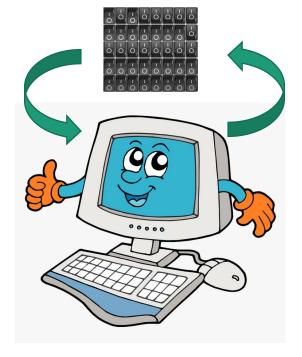

Rows (RAS)

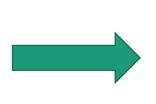

### Computers are Walls of Switches

That's all they are!

Something of interest in the real world (a scene, an object, a person, etc

Encode it so a computer can understand it (0's and 1's)

Have the happy computer do something to the representation

Decode the bits back to something human-understandable

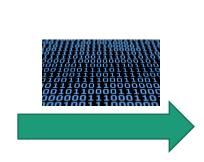

Effect change in the real world

### Computers are Walls of Switches

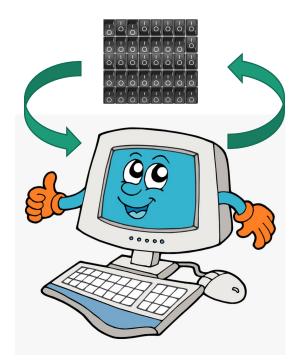

That's all they are!

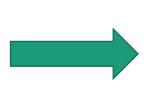

Something of interest in the real world (a scene, an object, a person, etc

Encode it so a computer can understand it (0's and 1's)

Have the happy computer do something to the representation (following our programs)

Decode the bits back to something human-understandable

Effect change in the real world

# Encoding "Stuff" in Memory

• If a computer is only a bunch of switches (a bunch of 0's and 1's)... how can it make sense of anything?

Let's start with a small example, and build up

## A Single Switch

- One bit of memory. A single 0 or 1
- Could store something useful
  - If there is a fire or not
  - If I am hungry or not
- Represents something as being true or false
- In C++, this is a boolean (bool) data type

## A Single Switch

```
#include <iostream>
 3
    using namespace std;
4
    int main(){
 6
 7
        bool isHungry = false; // not currently hungry
8
9
        return 0;
10
```

• Shhhhh line 7 actually uses 8 bits! (one byte) ... because our memory addresses are per byte and not per bit. Oh well. Memory is cheap now

13

#### What about numbers?

• Easy!

• I can just store a zero by using 0 (switch is off)

And I can store a 1 by using 1 (switch is on)

#### What about numbers BIGGER than 1?

• Huh

• What to do

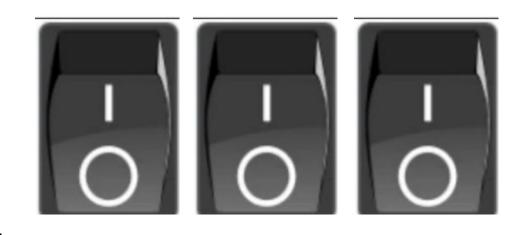

#### What about numbers BIGGER than 1?

What if I used multiple switches?

And count up the number of "on" switches?

- THIS COULD WORK
  - ON-ON (1+1) would be 2
  - ON-ON-ON (1+1+1) would be 3
  - ON-ON-ON (1+1+1+1) would be 4

# What's wrong with just adding up the 1's?

It throws away memory.

00111 would be the same as 11001

• We could come up with a system that makes every change

meaningful

• It's called binary!

Number (decimal)	Binary	Our weird system						
0	0	0						
1	1	1						
2	10	11						
3	11	111						
4	100	1111						
5	101	11111						
•••								
255	11111111	111111111111111111111111111111111111111						
256	10000000	111111111111111111111111111111111111111						

# Cool! We can now store any number in memory

• This is huge.

• In C++, we generally use 8 byte (64 bits) ints (integers)

\*decimals, anyone?

```
#include <iostream>

using namespace std;

int main(){

int currentAge = 28;

return 0;
}
```

#### Storing decimals (floating point) in memory

- How can I store 0.5 in memory?
- This is a challenge...
- Fortunately we can store two integers and turn them into a decimal
- This is in the weeds... but know that floating point representations are NOT EXACT

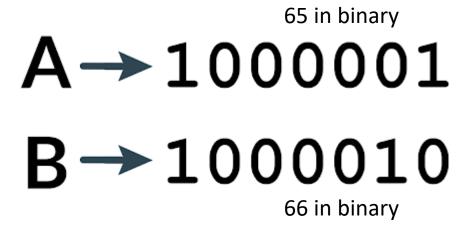

#### Representation of Floating-Point numbers

$$-1^{S} \times M \times 2^{E}$$

Bit No	Size	Field Name
31	1 bit	Sign (S)
23-30	8 bits	Exponent (E)
0-22	23 bits	Mantissa (M)

#### What about... letters?

 Well, we already know how to store whole numbers... let's just do that

#### Storing letters in memory

 Well, we already know how to store numbers... let's just do that  $A \longrightarrow 100001$   $B \longrightarrow 100001$   $_{66 \text{ in binary}}$ 

• 65 ????

#### Storing words and sentences in memory

#### "michael" encoded in Binary Code is:

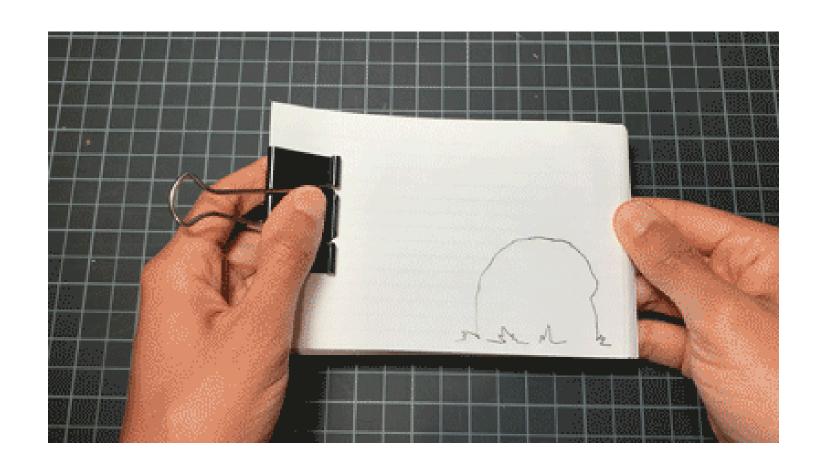

m (109) i (105) c (99) h (104) a (97) e (101) l(108)

#### What about... images?

Color images have multiple layers RGB, CMYK, etc. with each layer representing pixel values for that color.

#### What about... movies?

### What about... people?

- We can pick out things we care about (name, age, etc) and encode those with methods we know how
- We can take photos of people...
- We can 3D scan people and store their physical geometry?
- Can we represent an individual's mind in a computer?

### What about... people?

- What is a "person" to Facebook?
  - Your likes, activity, friends, etc.
- Spotify?
- TikTok?
- The field of AI / Machine learning is trying to do more...
   store intelligence in a computer
- One of you might figure this out 27

### Computers are Walls of Switches

## How do we give instructions to the computer?

• Programming of course, but computers don't know C++... (humans do).

• Humans have built tools to translate C++ into computer speak (machine language)... compiler/assembler

# Levels of Program Code

```
High Level Language
(C++, Python, Java)
```

```
temp = v[k];
v[k] = v[k+ I];
v[k+ I] = temp;
```

Compiler

(ARM, MIPS, x86)

Assembler

```
Iw $t0, 0($2)
Iw $t1, 4($2)
sw $t1, 0($2)
sw $t0, 4($2)
```

**Machine Language** 

```
0000 1001 1100 0110 1010 1111 0101 1000 1010 1111 0101 1000 0000 1001 1100 0110 1100 0110 1100 0000 1001 0101 1000 0000 1001
```

## How do we give instructions to the computer?

We are writing a book for the computer (processor) to read.

 The book contains instructions on which switches should be looked at, which switches should be flipped, and how to organize the switches

Let's first look at organizing the wall of switches with variables

# Variables

#### Variables

#### A variable:

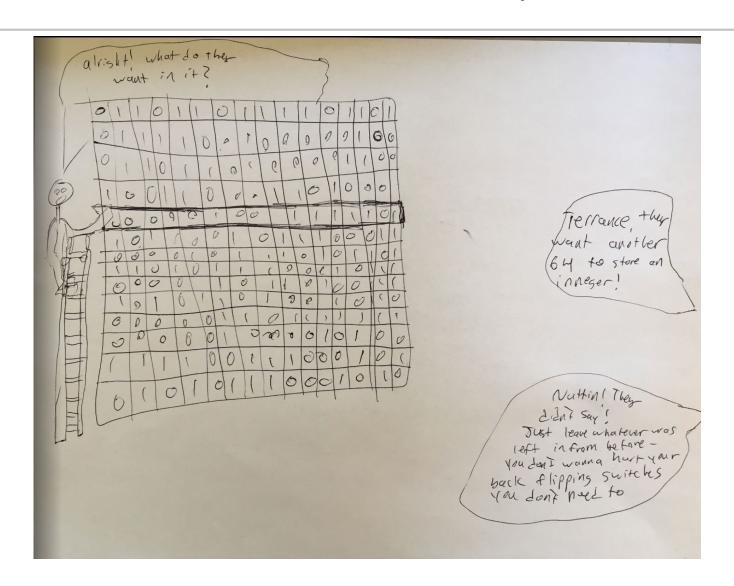

- is used to **store** information (the **value/contents** of the variable)
  - can contain one piece of information at a time.
- has an identifier (the name of the variable)
- The programmer picks a good name
  - A good name describes the contents of the variable or what the variable will be used for
  - has a type (more about this very soon)

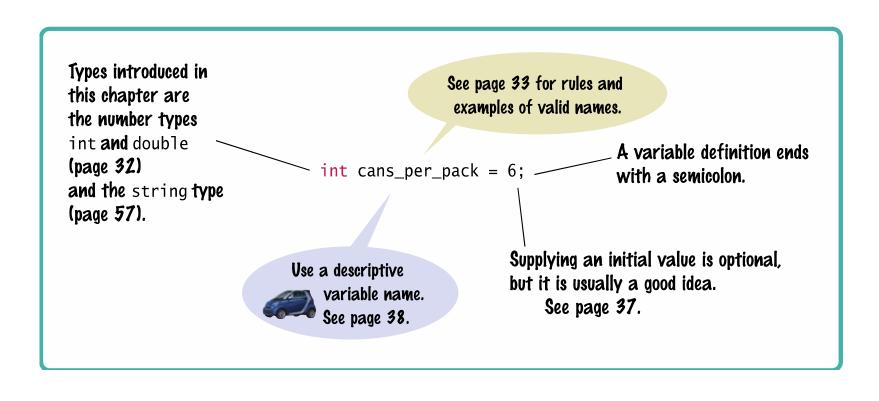

#### Variable Definitions

• When creating variables, the programmer specifies the **type** of information to be stored.

- A variable is often given an initial value.
  - Initialization is putting a value into a variable when the variable is created.
  - Initialization is not required.

# Variables: chunks of memory

Variable Definitions

#### Variable Definitions: example

The following statement defines a variable:

```
int cans per pack = 6;
```

cans\_per\_pack is the variable's name.

int indicates that the variable cans\_per\_pack will hold integers. Other variable types covered later will hold strings and floating-point numbers.

= 6 indicates that the variable cans\_per\_pack will initially contain the value 6.

Like all statements, it must end with a semicolon.

#### To the CodeMobile

# Variable Definitions: more examples

Table 1: Variable Definitions in C++		
	Comment	
int cans = 6;	Defines an integer variable and initializes it with 6.	
int total = cans + bottles;	The initial value need not be a constant. (Of course, cans and bottles must have been previously defined.)	
int bottles = "10";	Error: You cannot initialize an int variable with a string.	
int bottles;	Defines an integer variable without initializing it. This can be a cause for errors—see Common Error 2.2.	
int cans, bottles;	Defines two integer variables in a single statement. In this book, we will define each variable in a separate statement.	
bottles = 1;	Caution: The type is missing. This statement is not a definition but an assignment of a new value to an existing variable—see Section 2.1.4.	

Table 2: Number Literals		
	Туре	Comment
6	int	An integer has no fractional part.
<b>–</b> 6	int	Integers can be negative.
0	int	Zero is an integer.
0.5	double	A number with a fractional part has type double.
1.0	double	An integer with a fractional part .0 has type double.
1E6	double	A number in exponential notation: $1 \times 106$ or $1000000$ . Numbers in exponential notation always have type double.
2.96E-2	double	Negative exponent: 2.96 × 10–2 = 2.96 / 100 = 0.0296
100,000		Error: Do not use a comma as a decimal separator.
3 1/2		Error: Do not use fractions; use decimal notation: 3.5.

Table 3: Variable Names		
Variable Name	Comment	
can_volume1	Variable names consist of letters, numbers, and the underscore character.	
X	In mathematics, you use short variable names such as x or y. This is legal in C++, but not very common, because it can make programs harder to understand (see Programming Tip 2.1)	
Can_volume	Caution: Variable names are case sensitive. This variable name is different from can_volume.	
6pack	Error: Variable names cannot start with a number.	
can volume	Error: Variable names cannot contain spaces.	
double	Error: You cannot use a reserved word as a variable name.	
ltr/fl.oz	Error: You cannot use symbols such as . or /	

### The Assignment Statement

- The contents in variables can "vary" over time (hence the name!).
- Variables can be changed by
  - assigning to them
    - The assignment statement ("=")
  - using the increment or decrement operator (++, --)
  - inputting into them
    - The input statement ("cin")

#### Assignment Statement Example

• An assignment statement stores a new value in a variable, replacing the previously stored value.

• This assignment statement changes the value stored in cans\_per\_pack to be 8.

The previous value is replaced.

### Assignment Statement: defining vs. assigning

There is an important difference between a variable definition and an assignment statement:

```
int cans_per_pack = 6; // Variable definition
...
cans per pack = 8; // Assignment statement
```

- The first statement is the *definition* of cans\_per\_pack.
- The second statement is an assignment statement.
  - An existing variable's contents are replaced.
- A variable's definition must occur <u>only once</u> in a program. The same variable may be in several assignment statements in a program.

## The Meaning of the Assignment = Symbol

- The = in an assignment does not mean the left hand side is equal to the right hand side as it does in math.
- = is an instruction to do something:
   copy the value of the expression on the right into the variable on the left.
- Consider what it would mean, mathematically, to state:

```
counter = counter + 2;
```

counter EQUALS counter + 2

#### Assignment Examples

```
counter = 11; // set counter to 11
counter = counter + 2; // increment
```

- 1. First statement assigns 11 to counter
- 2. Second statement looks up what is currently in the variable counter (11)
- 3. Then it adds 2 and copies the result of the addition into the variable on the left, changing counter to 13

#### Constants

- Sometimes the programmer knows certain values just from analyzing the problem
  - For this kind of information, use the reserved word const.
- The reserved word const is used to define a constant.
- A const is a "variable" whose contents cannot be changed and must be set when created.

(Most programmers just call them constants, not variables.)

• Constants are commonly written using capital letters to distinguish them visually from regular variables:

```
const double BOTTLE VOLUME = 2;
```

#### Constants Prevent Unclear Numbers in Code

Another good reason for using constants:

```
double volume = bottles * 2;
```

What does that 2 mean?

If we use a constant there is no question:

```
double volume = bottles * BOTTLE_VOLUME;
```

### Constants Prevent Unclear Numbers in Code (2)

And still another good reason for using constants:

```
double bottle_volume = bottles * 2;
double can_volume = cans * 2;
```

What does that 2 mean?

— WHICH 2?

It is not good programming practice to use magic numbers. Use **constants**.

## Constants Prevent Unclear Numbers in Code (3)

And it can get even worse ...

Suppose that the number 2 appears hundreds of times throughout a five-hundred-line program?

Now we need to change the BOTTLE\_VOLUME to 2.23 (because we are now using a bottle with a different shape)

How to change only some of those 2's?

#### Constants again

Constants to the rescue!

```
const double BOTTLE_VOLUME = 2.23;
const double CAN_VOLUME = 2;
...
double bottle_volume = bottles * BOTTLE_VOLUME;
double can_volume = cans * CAN_VOLUME;
```

#### Comments

- Comments are explanations for human readers of your code (other programmers or your instructor).
- The compiler ignores comments completely.
- A leading double slash // tells the compiler the remainder of this line is a comment, to be ignored
- For example,

```
double can volume = 0.355; // Liters in a 12-ounce can
```

#### Comments: // or /\* multi-line \*/

Comments can be written in two styles:

• Single line:

```
double can_volume = 0.355; // Liters in a 12-ounce can
```

The compiler ignores everything after // to the end of line

• Multiline for longer comments, where the compiler ignores everything between  $/\star$  and  $\star/$ 

```
/*
   This program computes the volume (in liters)
   of a six-pack of soda cans.
*/
```

#### Common Error: Using Undefined Variables

You must define a variable before you use it for the first time.

For example, the following sequence of statements would not be legal:

```
double can_volume = 12 * liter_per_ounce;
double liter_per_ounce = 0.0296;
```

Statements are compiled in top to bottom order.

When the compiler reaches the first statement, it does not know that liter\_per\_ounce will be defined in the next line, and it reports an error.

#### Common Error: Using Uninitialized Variables

- Initializing a variable is not required, but there is always a value in every variable, even uninitialized ones.
- Some value will be there, left over from some previous calculation or simply the random value there when the transistors in RAM were first turned on.

```
int bottles; // Forgot to initialize
int bottle_volume = bottles * 2;
```

What value would be output from the following statement? cout << bottle\_volume << endl;

# **Errors!**

#### Common Error – Omitting Semicolons errors

Omitting a semicolon (or two), in this case at the end of the cout statement

```
#include <iostream>
using namespace std;
int main()
{
    cout << "Hello, World!" << endl
    return 0;
}</pre>
```

#### Syntax errors

Without that semicolon you actually wrote:

which thoroughly confuses the compiler with the endl immediately followed by the return!

- This is a *compile-time error* or *syntax error*.
- A syntax error is a part of a program that does not conform to the rules of the programming language.

#### Errors: Misspellings

• Suppose you (accidentally of course) wrote:

```
cot << "Hello World!" << endl;</pre>
```

- This will cause a compile-time error and the compiler will complain that it has no clue what you mean by cot.
- The exact wording of the error message is dependent on the compiler, but it might be something like

<sup>&</sup>quot;Undefined symbol cot" or "Unknown identifier".

#### How many errors?

- The compiler will not stop compiling, and will most likely list lots and lots of errors that are caused by the first one it encountered.
- You should fix only those error messages that make sense to you, starting with the first one, and then recompile (after SAVING, of course!).

#### Logic Errors

#### Consider this:

```
cout << "Hollo, World!" << endl;</pre>
```

- Logic errors or run-time errors are errors in a program that compiles (the syntax is correct), but executes without performing the intended action.
- The programmer must thoroughly inspect and test the program to guard against logic errors.
  - Testing and repairing a program usually takes more time than writing it in the first place, but is essential!

#### Errors: Run-Time Exceptions

Some kinds of run-time errors are so severe that they generate an *exception*: a signal from the processor that aborts the program with an error message.

For example, if your program includes the statement

Your program may terminate with a "divide by zero" exception.

## Errors: extra or misspelled main() function

- Every C++ program must have one and only one main function.
- Most C++ programs contain other functions besides **main** (more about functions next week).

#### Errors: C++ is Case Sensitive

C++ is *case sensitive*. Typing:

int Main()

will compile but will not link.

A link-time error occurs here when the linker cannot find the main function — because you did not define a function named main. (Main is fine as a name but it is not the same as main and there has to be one main somewhere.)

If you want to learn more about the build process, read this. The content in this webpage is not a part of the syllabus and will not be on any course related assignments.

## Making your Program Readable (by Humans)

C++ has *free-form layout* 

```
int main() {cout<<"Hello, World!"<<endl;return 0;}</pre>
```

will compile (but is practically impossible to read)

A good program is readable:

- code spaced across multiple lines, one statement per line
- follows indentation conventions
